2024 Fall Semester

Utilities, rational decisions

Dr. Gábor Hullám

Slides Adapted from Berkeley CS188, from Dan Klein and Pieter Abbeel http://ai.berkeley.edu

Budapesti Műszaki és Gazdaságtudományi Egyetem Villamosmérnöki és Informatikai Kar Mesterséges Intelligencia és Rendszertervezés Tanszék

Artificial intelligence lectures

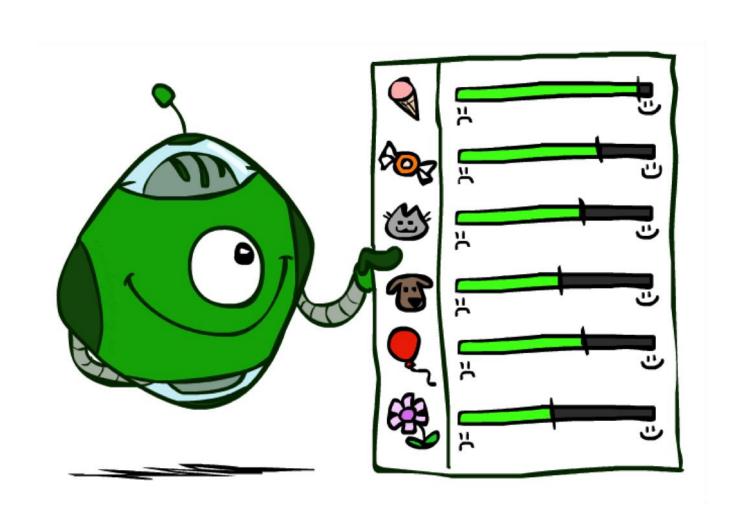

Az előadás diái az AIMA könyvre épülve (http://aima.cs.berkeley.edu) készültek a University of California, Berkeley mesterséges intelligencia kurzusának anyagainak felhasználásával (http://ai.berkeley.edu).

These slides are based on the AIMA book (http://aima.cs.berkeley.edu) and were adapted from the AI course material of University of California, Berkeley (http://ai.berkeley.edu).

Utilities

Maximum Expected Utility

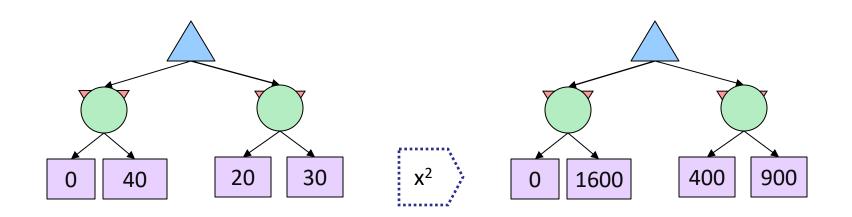

- Why should we average utilities? Why not minimax?
- Principle of maximum expected utility:
 - A rational agent should chose the action that maximizes its expected utility, given its knowledge

- Where do utilities come from?
- How do we know such utilities even exist?
- How do we know that averaging even makes sense?
- What if our behavior (preferences) can't be described by utilities?

What Utilities to Use?

- For worst-case minimax reasoning, terminal function scale doesn't matter
 - We just want better states to have higher evaluations (get the ordering right)
 - We call this insensitivity to monotonic transformations
- For average-case expectimax reasoning, we need magnitudes to be meaningful

Utilities

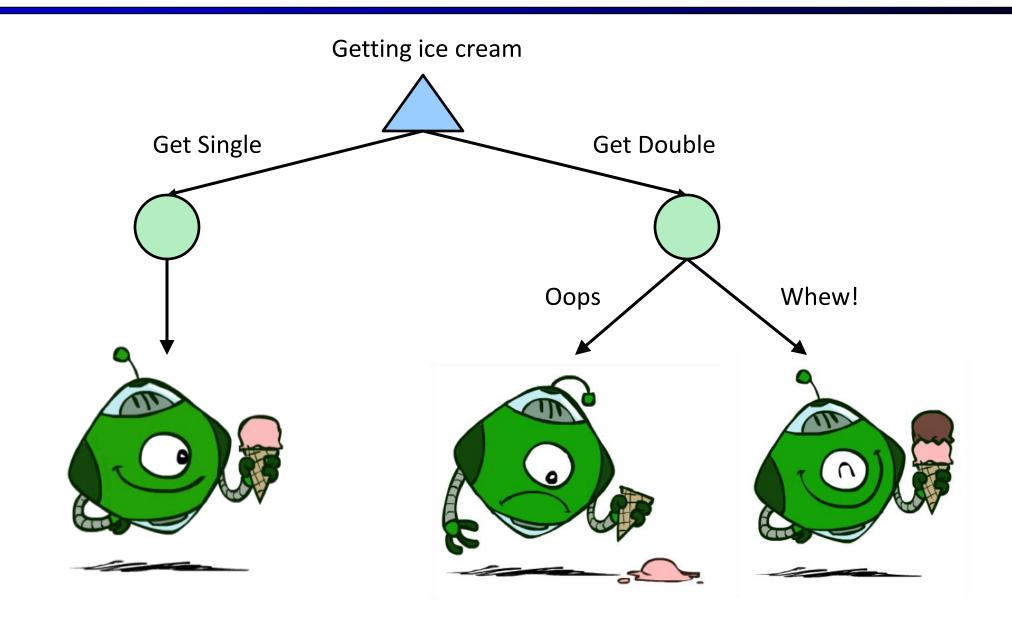

- Utilities are functions from outcomes (states of the world) to real numbers that describe an agent's preferences
- Where do utilities come from?
 - In a game, may be simple (+1/-1)
 - Utilities summarize the agent's goals
 - Theorem: any "rational" preferences can be summarized as a utility function
- We hard-wire utilities and let behaviors emerge
 - Why don't we let agents pick utilities?
 - Why don't we prescribe behaviors?

Utilities: Uncertain Outcomes

Preferences

An agent must have preferences among:

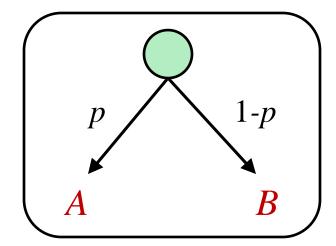

- Prizes: A, B, etc.
- Lotteries: situations with uncertain prizes

$$L = [p, A; (1-p), B]$$

A Prize

A Lottery

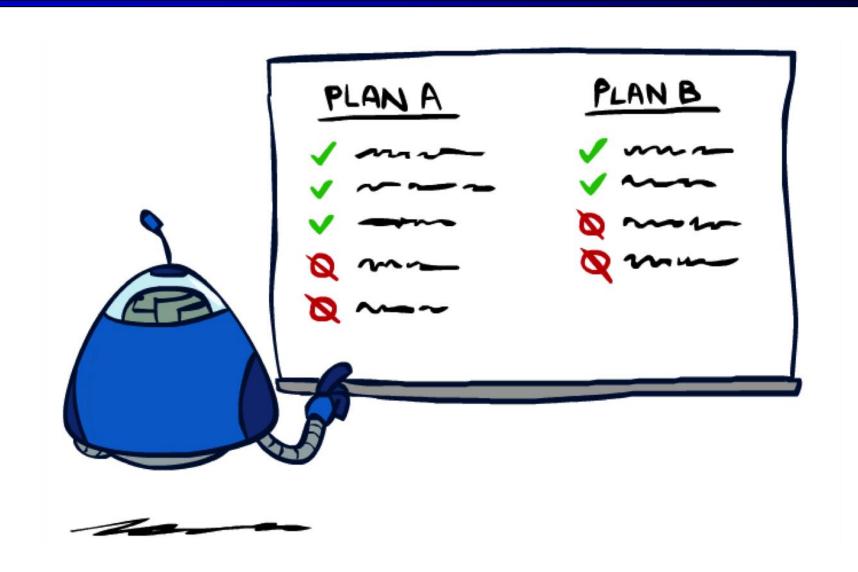

Notation:

- Preference: $A \succ B$
- Indifference: $A \sim B$

Rationality

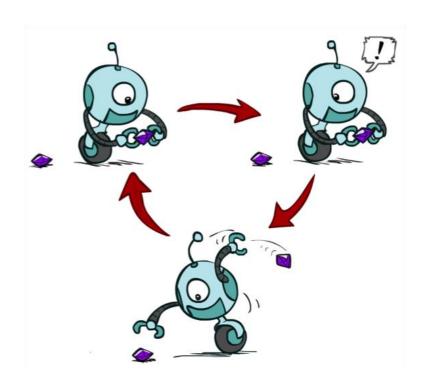

Rational Preferences

We want some constraints on preferences before we call them rational, such as:

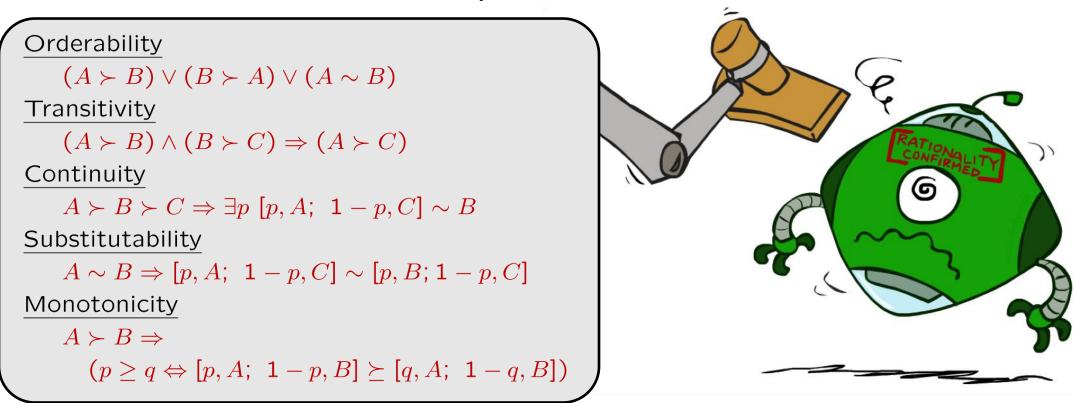

Axiom of Transitivity:
$$(A \succ B) \land (B \succ C) \Longrightarrow (A \succ C)$$

- For example: an agent with intransitive preferences can be induced to give away all of its money
 - If B > C, then an agent with C would pay (say) 1 cent to get B
 - If A > B, then an agent with B would pay (say) 1 cent to get A
 - If C > A, then an agent with A would pay (say) 1 cent to get C

Rational Preferences

The Axioms of Rationality

Theorem: Rational preferences imply behavior describable as maximization of expected utility

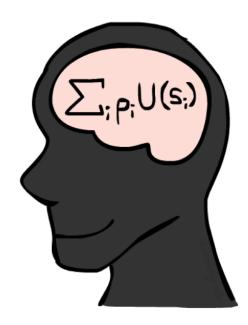

MEU Principle

- Theorem [Ramsey, 1931; von Neumann & Morgenstern, 1944]
 - Given any preferences satisfying these constraints, there exists a real-valued function U such that:

$$U(A) \ge U(B) \Leftrightarrow A \succeq B$$

 $U([p_1, S_1; \dots; p_n, S_n]) = \sum_i p_i U(S_i)$

- Maximum expected utility (MEU) principle:
 - Choose the action that maximizes expected utility
 - Note: an agent can be entirely rational (consistent with MEU) without ever representing or manipulating utilities and probabilities
 - E.g., a lookup table for perfect tic-tac-toe, a reflex vacuum cleaner

Human Utilities

Utility Scales

- Normalized utilities: $u_{+} = 1.0$, $u_{-} = 0.0$
- Micromorts: one-millionth chance of death, useful for paying to reduce product risks, etc.
- QALYs: quality-adjusted life years, useful for medical decisions involving substantial risk
- Note: behavior is invariant under positive linear transformation

$$U'(x) = k_1 U(x) + k_2$$
 where $k_1 > 0$

 With deterministic prizes only (no lottery choices), only ordinal utility can be determined, i.e., total order on prizes

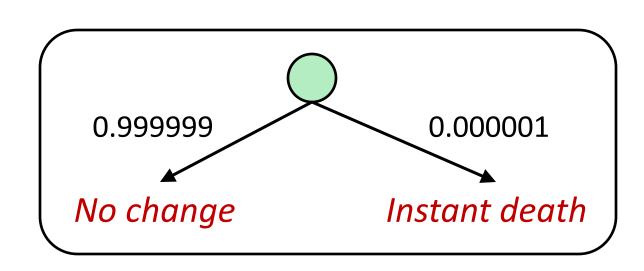

Human Utilities

- Utilities map states to real numbers. Which numbers?
- Standard approach to assessment (elicitation) of human utilities:
 - Compare a prize A to a standard lottery L_p between
 - "best possible prize" u₊ with probability p
 - "worst possible catastrophe" u_ with probability 1-p
 - Adjust lottery probability p until indifference: A ~ L_p
 - Resulting p is a utility in [0,1]

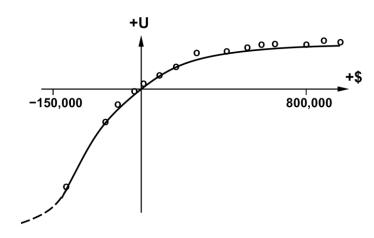

Money

- Money <u>does not</u> behave as a utility function, but we can talk about the utility of having money (or being in debt)
- Given a lottery L = [p, \$X; (1-p), \$Y]
 - The expected monetary value EMV(L) is p*X + (1-p)*Y
 - U(L) = p*U(\$X) + (1-p)*U(\$Y)
 - Typically, U(L) < U(EMV(L))
 - In this sense, people are risk-averse
 - When deep in debt, people are risk-prone

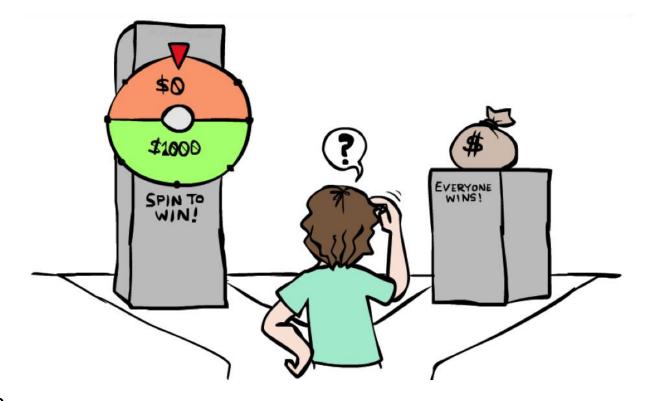

Example: Insurance

- Consider the lottery [0.5, \$1000; 0.5, \$0]
 - What is its expected monetary value? (\$500)
 - What is its certainty equivalent?
 - Monetary value acceptable in lieu of lottery
 - \$400 for most people
 - Difference of \$100 is the insurance premium
 - There's an insurance industry because people will pay to reduce their risk
 - If everyone were risk-neutral, no insurance needed!
 - It's win-win: you'd rather have the \$400 and the insurance company would rather have the lottery (their utility curve is flat and they have many lotteries)

Example: Human Rationality?

Famous example of Allais (1953)

■ A: [0.8, \$4k; 0.2, \$0] **(**

■ B: [1.0, \$3k; 0.0, \$0]

■ C: [0.2, \$4k; 0.8, \$0]

■ D: [0.25, \$3k; 0.75, \$0]

- Most people prefer B > A, C > D
- But if U(\$0) = 0, then
 - $B > A \Rightarrow U(\$3k) > 0.8 U(\$4k)$
 - $C > D \Rightarrow 0.8 U(\$4k) > U(\$3k)$
